Comments in python

A comment is a line in the python program that the computer ignores. It's written only for human - to explain what the code does. It make the code easier to understand, debug & maintain.

Types of comments in python.

1. Single line comment

   Syntax : start with #

   Example : # This is a single-line comment.

2. Multi-line comment

   Syntax : Use triple quotes

   ''' or """

   Example : python\n''' \n this is a multi-line comment\n It can cover multiple lines\n ''' \n

Example :

```
→ # This program adds two numbers
   a = 10  # first no
   b = 20  # second no
   Sum = a + b  # calculate sum
   print (" Sum = ", Sum)  # display result.
→ '''
   This is a multi-line comment
   in python using triple single quotes
   '''
   Print (" Hello world ")
```

Keywords in python :

They are the predefined words to perform a specific task

Ex : if, for, else, break, False, True, None, as ... Etc..

→ These keywords are not used as identifiers (variables, function name...)

Variables.

A Variable is a name that stores a value in the computer memory. or they are place holders which holds any kind of value & they are represented by variable names.

Ex: pi = 3.14
print (pi)

Rules for Variable declaration:

→ Must start with upper or lower case or underscore (_).
→ It can be single alphabet or string or alphanumeric.
→ We can use dual words as single variable but they should seperated by _ (underscore)
→ Cannot start with a number
→ No spaces or special characters (@, #, $ ..) apart from _
→ Dont use the python keywords (like for, if, class)..

Valid Variable declaration:

1) A = 6
2) a = 3
3) place = "mysore"
4) _place = "mysore"
5) student_name = "sanjana"
6) num1 = 26
7) num2 = 36.

Invalid Variable declaration:

1) stu name = "sanjana"
2) 1num = 23
3) @place = "mysore"

User input function / Read from user in python.

In python, the input() function is used to read from the user. It allows the user to enter information through the keyboard.

Syntax: variable = input ("Enter something:")
Example: name = input ("Enter your name:")
print ("My name is ", name)

→ Reading numbers from the user.

By default the input() function reads data as a string

(str) even if the user enters a number.

To read an integer, use int().

Ex: a = int(input("Enter first number:"))
b = int(input("Enter second number:"))
print("Sum =", a+b)

Reading a decimal number

Use float() to read decimal values.

Ex: price = float(input("Enter the price:"))
print(price)
